An introduction to some EGO-like algorithms for constrained / multi-objective / noisy problems

Julien Bect

Laboratoire des signaux et systèmes, Gif-sur-Yvette, France

École-chercheurs Mexico: "Analyse de sensibilité, métamodélisation et optimisation de modèles complexes"

La Rochelle, 30 mars 2018

Where do you think you're going ? (M. Knopfler, 1979)

In this lecture we will...

- introduce some "EGO like" (Bayesian optimization) algorithms for other types of optimization problems,
- present some (toy) examples in R and Matlab/Octave

Types of problems that we will consider (if time permits...)

- deterministic simulators
  - inequality-constrained problems
  - multi-objective problems
- stochastic simulators
  - optimization of the mean response

#### Disclaimers

- This is just the tip of the iceberg...
  - gradients (e.g., with adjoint codes)
  - "hidden constraints": handling simulation failures
  - equality constraints
  - robust optimization
  - estimating extreme level sets / probabilities / quantiles

<ロ><日><日><日><日><日><日><日><日><日><日><日><日><10</td>

# Recap: the Expected Improvement (EI) criterion

Illustration borrowed from slides by Emmanuel Vazquez, Ecole d'été CEA-EDF-INRIA, July 2017

7/42

We have denoted the current minimum as

$$m_n^{\star} = \min_{i \leq n} Z_i.$$

The improvement at x is defined as

$$(m_n^{\star}-Z(x))_+=egin{cases} 0 & ext{if } Z(x)\geq m_n^{\star}\ m_n^{\star}-Z(x) & ext{otherwise,} \end{cases}$$

We have denoted the current minimum as

$$m_n^{\star} = \min_{i \leq n} Z_i.$$

The improvement at x is defined as

$$(m_n^\star - Z(x))_+ = egin{cases} 0 & ext{if } Z(x) \geq m_n^\star \ m_n^\star - Z(x) & ext{otherwise,} \end{cases}$$

▶ If we select a particular x as  $x_{n+1}$ , we have  $Z_{n+1} = Z(x)$  and

$$(m_n^{\star}-Z(x))_+ = m_n^{\star}-m_{n+1}^{\star}.$$

▶ Now set  $Z^* = \min_x Z(x)$  and rewrite (again with  $x_{n+1} = x$ )

$$(m_n^{\star} - Z(x))_+ = (m_n^{\star} - Z^{\star}) - (m_{n+1}^{\star} - Z^{\star})$$
(1)

< □ > < □ > < □ > < Ξ > < Ξ > Ξ の Q @ 9/42

▶ Now set  $Z^* = \min_x Z(x)$  and rewrite (again with  $x_{n+1} = x$ )

$$(m_n^{\star} - Z(x))_+ = (m_n^{\star} - Z^{\star}) - (m_{n+1}^{\star} - Z^{\star})$$
(1)

Taking the expectation at time n, we get

$$\operatorname{EI}_{n}(x) = \operatorname{E}_{n}(m_{n}^{\star} - Z^{\star}) - \operatorname{E}_{n}(m_{n+1}^{\star} - Z^{\star} \mid x_{n+1} = x)$$

▶ Now set  $Z^* = \min_x Z(x)$  and rewrite (again with  $x_{n+1} = x$ )

$$(m_n^{\star} - Z(x))_+ = (m_n^{\star} - Z^{\star}) - (m_{n+1}^{\star} - Z^{\star})$$
(1)

Taking the expectation at time n, we get

$$\operatorname{EI}_{n}(x) = \underbrace{\operatorname{E}_{n}(m_{n}^{\star} - Z^{\star})}_{\operatorname{call this } H_{n}} - \operatorname{E}_{n}(m_{n+1}^{\star} - Z^{\star} \mid x_{n+1} = x)$$

•  $H_n \ge 0$  and, when  $H_n$  is small, then  $Z^* \approx m_n^*$  with high proba.

Interpretation

 $H_n$  can be seen as a measure of uncertainty about  $Z^*$ , at time n

One last effort... recall the law of total expectation:

$$\mathsf{E}_n(U) = \mathsf{E}_n(\mathsf{E}_{n+1}(U)), \quad \text{for any r.v. } U.$$

• One last effort... recall the law of total expectation:

$$\mathsf{E}_{n}\left(U\right)=\mathsf{E}_{n}\left(\mathsf{E}_{n+1}\left(U\right)\right),\qquad\text{for any r.v. }U.$$

We can thus rewrite the EI criterion as

$$EI_n(x) = H_n - E_n(H_{n+1} | x_{n+1} = x)$$

One last effort... recall the law of total expectation:

$$\mathsf{E}_{n}\left(U\right) = \mathsf{E}_{n}\left(\mathsf{E}_{n+1}\left(U\right)\right), \qquad \text{for any r.v. } U.$$

We can thus rewrite the EI criterion as

$$EI_n(x) = H_n - E_n(H_{n+1} | x_{n+1} = x)$$

#### Interpretation

- The EGO algorithm minimizes greedily, at each step, the expected uncertainty at the next step.
- This is a particular case of a Stepwise Uncertainty Reduction (SUR) algorithm.

- Assume that you want to estimate a certain Qol
  - Qol = Quantity of Interest
  - Example:  $x^*$  or  $f(x^*)$  in a single-objective optim problem

- Assume that you want to estimate a certain Qol
  - Qol = Quantity of Interest
  - Example:  $x^*$  or  $f(x^*)$  in a single-objective optim problem
- Then the SUR approach consists of the following steps

SUR approach

1. Choose a prior: f is seen as a samplepath from a GP Z

- Assume that you want to estimate a certain Qol
  - Qol = Quantity of Interest
  - Example:  $x^*$  or  $f(x^*)$  in a single-objective optim problem
- Then the SUR approach consists of the following steps

SUR approach

- 1. Choose a prior: f is seen as a samplepath from a GP Z
- 2. Choose a "measure of uncertainty"  $H_n$

- Assume that you want to estimate a certain Qol
  - Qol = Quantity of Interest
  - Example:  $x^*$  or  $f(x^*)$  in a single-objective optim problem
- Then the SUR approach consists of the following steps

#### SUR approach

- 1. Choose a prior: f is seen as a samplepath from a GP Z
- 2. Choose a "measure of uncertainty"  $H_n$
- 3. Iterate (possibly after some exploratory initial design)

 $x_{n+1} = \operatorname{argmin}_{x} \mathsf{E}_{n} (H_{n+1} \mid x_{n+1} = x)$ 

or, equivalently,  $x_{n+1} = \operatorname{argmax}_{x} H_n - \mathsf{E}_n (H_{n+1} \mid x_{n+1} = x)$ .

### Inequality-constrained problems

- Consider a single-objective, inequality-contrained problem:
  - minimize f(x)
  - under the constraints  $x \in \mathbb{X}$  and  $g_j(x) \leq 0, \ 1 \leq j \leq q$
- where
  - X is a nice, known compact subset of  $\mathbb{R}^d$  (e.g.,  $\mathbb{X} = [0; 1]^d$ )

◆□ ▶ ◆□ ▶ ◆ ■ ▶ ◆ ■ ▶ ● ■ ⑦ Q ○ 15/42

- $f, g_1, \ldots, g_q : \mathbb{X} \to \mathbb{R}$
- both f and the g<sub>j</sub>'s are expensive to evaluate

### Inequality-constrained problems

- Consider a single-objective, inequality-contrained problem:
  - minimize f(x)
  - under the constraints  $x \in \mathbb{X}$  and  $g_j(x) \leq 0$ ,  $1 \leq j \leq q$
- where
  - X is a nice, known compact subset of  $\mathbb{R}^d$  (e.g.,  $\mathbb{X} = [0; 1]^d$ )
  - $f, g_1, \ldots, g_q : \mathbb{X} \to \mathbb{R}$
  - both f and the g<sub>j</sub>'s are expensive to evaluate
- Important: now there are several "unknown" functions !
  - We will need to use q + 1 GP models
  - Usually assumed independent  $\Rightarrow$  not really harder than one GP

### Inequality-constrained problems

- Consider a single-objective, inequality-contrained problem:
  - minimize f(x)
  - under the constraints  $x \in \mathbb{X}$  and  $g_j(x) \leq 0$ ,  $1 \leq j \leq q$
- where
  - X is a nice, known compact subset of  $\mathbb{R}^d$  (e.g.,  $\mathbb{X} = [0; 1]^d$ )
  - $f, g_1, \ldots, g_q : \mathbb{X} \to \mathbb{R}$
  - both f and the  $g_j$ 's are expensive to evaluate
- Important: now there are several "unknown" functions !
  - We will need to use q + 1 GP models
  - Usually assumed independent  $\Rightarrow$  not really harder than one GP
  - ▶ Notations:  $f \mapsto Z_o$  and  $g_j \mapsto Z_{c,j}$ ,  $1 \le j \le q$

# Measure of uncertainty ?

Recall the measure of uncertainty used in the EI case:

$$H_n = \mathsf{E}_n \left( m_n^\star - Z^\star \right)$$

How do we adapt this to inequality contraints ?

## Measure of uncertainty ?

Recall the measure of uncertainty used in the El case:

$$H_n = \mathsf{E}_n \left( m_n^\star - Z^\star \right)$$

How do we adapt this to inequality contraints ?

- Assume that at least one feasible solution is known
- Then the same  $H_n$  can be used, with

$$egin{aligned} m_n^\star &= \{Z_\mathrm{o}(x_i) \mid i \leq n \; ext{ s.t. } \; \forall j \leq q, \; Z_{\mathrm{c},j}(x_i) \leq 0\} \ Z^\star &= \{Z_\mathrm{o}(x) \mid x \in \mathbb{X} \; ext{ s.t. } \; \forall j \leq q, \; Z_{\mathrm{c},j}(x) \leq 0\} \end{aligned}$$

# Sampling criterion

► The corresponding "expected improvement" (to be maximized) is

$$EFI_n(x) = H_n - E_n (H_{n+1} | x_{n+1} = x)$$
  
=  $E_n \Big( \underbrace{(m_n^* - Z_o(x))_+}_{improvement} \cdot \underbrace{\mathbb{1}_{\forall j \le q, \ Z_{c,j}(x) \le 0}}_{feasibility} \Big)$ 

EFI = Expected Feasible Improvement (cf. DiceOptim)

WARNING: there is another Skywalker SUR crit. in DiceOptim

# Sampling criterion

► The corresponding "expected improvement" (to be maximized) is

$$EFI_n(x) = H_n - E_n (H_{n+1} | x_{n+1} = x)$$
  
=  $E_n \Big( \underbrace{(m_n^* - Z_o(x))_+}_{improvement} \cdot \underbrace{\mathbb{1}_{\forall j \le q, \ Z_{c,j}(x) \le 0}}_{feasibility} \Big)$ 

- EFI = Expected Feasible Improvement (cf. DiceOptim)
  - ► WARNING: there is another Skywalker SUR crit. in DiceOptim
- Assuming independent GPs, this simplifies to

$$\mathrm{EFI}_{n}(x) = \underbrace{\mathsf{E}_{n}\left(\left(m_{n}^{\star} - Z_{\mathrm{o}}(x)\right)_{+}\right)}_{\approx \text{ the "usual" El}} \cdot \underbrace{\prod_{j=1}^{q} \mathsf{P}_{n}\left(Z_{\mathrm{c},j}(x) \leq 0\right)}_{\text{probability of feasibility}}.$$

# Example

  - ► The response *S* (assumed scalar here) is a random variable

# Stochastic simulators in a nutshell

- Inside the box
  - A random vector U is generated during the simulation
  - Remark: most of the time, U is not directly accessible
- From the outside
  - ▶ The response *S* (assumed scalar here) is a random variable
  - The distribution of S depends on x

# Example: the MORET code (IRSN)

- MORET simulates neutron transport in fissile materials
- Output = effective multiplication factor (k-eff)
- ▶ Uses Monte Carlo methods ⇒ "noisy" estimate of k-eff

Source: MORET website, somewhere on the internet (sorry, no WIFI in my room last night...)

- Assume that we want to "minimize the output" S...
  - what does that even mean for a stochastic simulator ???
  - Recall: the output S is a random variable

- Assume that we want to "minimize the output" S...
  - what does that even mean for a stochastic simulator ???

▲□▶▲□▶▲□▶▲□▶ = のへで 29/42

- Recall: the output S is a random variable
- Let  $\pi_x^S$  denote the pdf of S at the input point  $x \in \mathbb{X}$

- Assume that we want to "minimize the output" S...
  - what does that even mean for a stochastic simulator ???
  - ▶ Recall: the output *S* is a random variable
- Let  $\pi_x^S$  denote the pdf of S at the input point  $x \in \mathbb{X}$

The simplest formulation that makes sense (?)

In the following we want to minimize the expected response:

Find  $x \in \mathbb{X}$  such that  $f(x) = \int s \pi_x^S(s) ds$  is minimal
